

MICROPOWER INSTRUMENTATION AMPLIFIER — POWER DRAIN $\leq 3\text{mW}$ WITH $\pm 5\text{V}$ SUPPLIES

Figure 3

In Figure 2, the OP-22 is used as a gated amplifier where power consumption and bandwidth are controllable. R_S can be selected for a specific lower-power operation or omitted so the amplifier can be completely shut down.

A micropower instrumentation amplifier that consumes less than 3mW with $\pm 5\text{V}$ supplies is shown in Figure 3. Offset voltage drift is less than $0.2\mu\text{V}/^\circ\text{C}$ and common-mode input range is $\pm 3\text{V}$ with CMRR of over 100dB at 60Hz .

Process control systems use two-wire $4\text{-}20\text{mA}$ current transmitters when sending analog signals through noisy environments. The "zero" or "offset" current of 4mA may be used to power the transmitter signal conditioning amplifiers and/or excite a d.c. transducer. This allows remote signal conditioning without having a remote power source. Power is provided at the receiving end where the signal current is monitored by a precision 50Ω resistor. The $4\text{-}20\text{mA}$ transmitter shown in Figure 4 has high stability, excellent linearity, and generates the $4\text{-}20\text{mA}$ current output. A 5V reference is available for powering transducers and micropower amplifiers at a maximum current of 2mA .

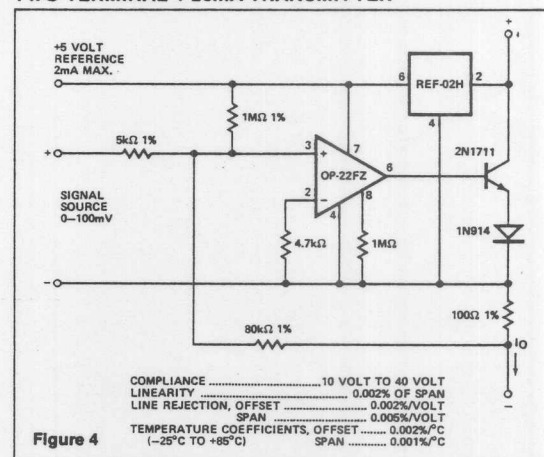

TWO TERMINAL $4\text{-}20\text{mA}$ TRANSMITTER
